

Batch: B1

Roll No.: 16010124080

Experiment / assignment / tutorial No. 3

TITLE : Student Result Processing System Using Classes in C++

AIM: To implement a student result processing system in C++ using classes and objects, focusing on encapsulation, constructors, and member functions

Expected OUTCOME of Experiment:

CO1: Apply the features of object oriented programming languages. (C++ and Java)

CO2: Explore arrays, vectors, classes and objects in C++ and Java

Books/ Journals/ Websites referred:

1. E. Balagurusamy, "Programming with Java", McGraw-Hill.
 2. E. Balagurusamy, "Object Oriented Programming with C++", McGraw-Hill.
-

Design a C++ program that creates and manages records of students using classes. Your program must:

1. Store data for multiple students.
2. Accept marks for 3 subjects.
3. Calculate total and average marks.
4. Display details of all students.

Department of Computer Engineering

Page No OOPM Sem III/July - Nov 2025

Batch: B1

Roll No.: 16010124080

Experiment / assignment / tutorial No. 3

5. Identify the student with the highest average.

Each student should have:

- Roll Number (int)
- Name (string)
- Marks in 3 subjects (float)
- Total (float)
- Average (float)

Requirements:

- Create a class **Student** with private data members.
- Use public member functions to:
 - Accept input (with a constructor or separate **input()** function).
 - Calculate total and average.
 - Display individual student data.
- Maintain multiple student records using an array of objects.

Variations/Modifications:

1. Modify your class to include student grades (A/B/C) based on average marks.
2. Write a function to sort the students by total marks in descending order.
3. Rewrite the program using dynamic memory allocation instead of a fixed-size array.
4. Add a static data member to count how many Student objects were created.
5. Add a search function to find and display the record of a student by roll number.

Pre Lab/ Prior Concepts:

Department of Computer Engineering

Page No OOPM Sem III/July - Nov 2025

Batch: B1

Roll No.: 16010124080

Experiment / assignment / tutorial No. 3

1. Basic Structure of a C++ Program

- Understanding the syntax of a C++ program: `#include`, `main()` function, return types.
- Use of headers like `<iostream>` and `using namespace std`.

2. Input and Output Operations

- Use of `cin` and `cout` for reading user input and displaying output.
- Formatting output using manipulators like `setw`, `fixed`, `setprecision` (if included).

3. Variables and Data Types

- Declaring variables of type `int`, `float`, `char`, and `string`.
- Understanding literals, constants, and data ranges.

4. Conditional Statements

- Use of `if`, `if-else`, and `switch` statements to perform decision-making based on input data.

5. Loops

- Implementation of `for`, `while`, and `do-while` loops.
 - Use cases: repeating input operations, iterating over arrays or records.

6. Arrays

- Declaring and using single-dimensional arrays.
 - Storing and accessing data for multiple entities like marks of students.

7. Functions

Department of Computer Engineering

Page No OOPM Sem III/July - Nov 2025

Batch: B1

Roll No.: 16010124080

Experiment / assignment / tutorial No. 3

- Writing reusable blocks of code using functions.
- Function declaration, definition, calling, and parameter passing (by value/reference).

8. Introduction to Classes in C++

- Definition and declaration of a class.
- Understanding the syntax for:
 - **Private** and **Public** access specifiers.
 - **Member variables** and **member functions**.
- Creating **objects** and accessing class members.

9. Constructors (Optional for your experiment)

- Understanding how constructors are used to initialize object data automatically.
- Syntax of default and parameterized constructors.

10. Arrays of Objects

- Using an array to store multiple objects of a class (e.g., `Student s[50];`).
- Accessing member functions for each object inside a loop.

Conclusion:

Date:22-08-25 Signature of faculty in-charge

Post Lab Descriptive Questions:

What is encapsulation, and how is it implemented in your program? What is the difference between a constructor and a regular member function? Why are data members declared **private** in a class?

Output:

1. Encapsulation is one of the fundamental principles of Object-Oriented Programming (OOP). It means wrapping data (variables) and methods (functions) that operate on the data into a single unit (class) and restricting direct access to some of the object's components.

Department of Computer Engineering

Page No OOPM Sem III/July - Nov 2025

K. J. Somaiya School of Engineering, Mumbai-77
(A Constituent College of Somaiya Vidyavihar University)
Department of Computer Engineering

The main goal is to hide the internal state of an object and only allow manipulation through well-defined interfaces (public functions).

This protects the integrity of the data by preventing external code from directly changing the object's internal state in unexpected ways.

In the program:

- The student's data members like rollNumber, name, marks, total, average, and grade are declared private.
- They cannot be accessed or modified directly outside the class.
- Instead, we provide public member functions like `input()`, `display()`, and `calculateTotalAndAverage()` which control how the data is accessed or modified.

This ensures that the data is accessed in a controlled and safe way, maintaining the object's integrity.

2. Constructor:

- Purpose: To initialize an object when it is created
- Name: Has the same name as the class and no return type (not even void)

- Called automatically: Called automatically when an object is created
- Number of calls: Called once per object creation
- Example: `Student()` initializes data members

Regular Member Function:

- Purpose: To perform operations on objects after creation
- Name: Can have any valid function name and must specify return type
- Called automatically: Must be called explicitly using the object •

Number of calls: Can be called multiple times as needed

- Example: `input()`, `display()` etc. used for other operations

3. Data members are declared private to:

- Protect data integrity: Prevent direct access/modification by outside code, which could lead to invalid or inconsistent states.

- Enforce encapsulation: Only allow controlled access via public member functions that can validate data or maintain class invariants.
- Enhance security: Hide implementation details, exposing only what is necessary.
- Enable flexibility: You can change the internal representation later without affecting code that uses the class, as external code interacts through a fixed interface.
